In combinatorics, a Davenport – Schinzel sequence is a sequence of symbols in which the number of times any two symbols may appear in alternation is limited. The maximum possible length of a Davenport – Schinzel sequence is bounded by the number of its distinct symbols multiplied by a small but nonconstant factor that depends on the number of alternations that are allowed. Davenport – Schinzel sequences were first defined in 1965 by Harold Davenport and Andrzej Schinzel to analyze linear ...

Davenport – Schinzel sequence - Wikipedia

Davenport – Schinzel sequences are named after Harold Davenport and Andrzej Schinzel, who applied them to certain problems in the theory of differential equations. They are finite sequences of symbols from a given alphabet , constrained by forbidding pairs of symbols from appearing in alternation more than a given number of times (regardless of what other symbols might separate them).

Davenport – Schinzel sequences, introduced by H. Davenport and A. Schinzel in the 1960s, are interesting and powerful combinatorial structures that arise in the analysis and construction of the lower (or upper) envelope of collections of univariate functions, and therefore have applications in a variety of geometric problems that can be reduced to computing such an envelope.

Davenport – Schinzel Sequence

Davenport-Schinzel sequences are deep and beautiful, simple but subtle combinatorial structures arising in a wide variety of geometric constructions. The remarkable story of their analysis is told in this book by two of the primary developers of the theory. The material is technically demanding and the style correspondingly uncompromising.

Davenport Schinzel sequences are sequences that do not contain forbidden alternating subsequences of certain length. They are a powerful combinatorial tool applicable in contexts which involve the calculation of the pointwise maximum or minimum of a collection of (univariate) continuous functions, and have thus many applications in computational geometry and related areas.

An (n,s) Davenport--Schinzel sequence, for positive integers n and s , is a sequence composed of n symbols with the properties that no two adjacent elements are equal, and that it does not contain, as a (possibly non-contiguous) subsequence, any alternation $a \cdot b \cdot a \cdot b \cdot \dots$ of length $s+2$ between two distinct symbols a and b .

An $(n; s)$ Davenport-Schinzel sequence, for positive integers n and s , is a sequence composed of n symbols with the properties that no two adjacent elements are equal, and that it does not contain, as a (possibly non-contiguous) subsequence, any alternation $a \Delta \Delta \Delta b \Delta \Delta \Delta a \Delta \Delta \Delta b \Delta \Delta \Delta$ of length $s + 2$ between two distinct symbols a and b .

Davenport-Schinzel sequences provide a powerful characterization of the structure that arises from the lower or upper envelope of a collection of functions. The lower envelope of five functions is depicted in Figure 6.42. Such envelopes arise in many problems throughout computational geometry, including many motion planning problems.

It is known that such sequences have length at most $n^{2 \cdot (n)} O(1)$, where \cdot is the inverse-Ackermann function and the $O(1)$ depends on \cdot . We resolve a number of open problems on the extremal properties of generalized Davenport–Schinzel sequences.
